

Data structure general format

Node declaration- (think hard about the node. So visualise without lines)

```
Struct [dataType]Node {  
    //data stored in Node eg- Object/value  
    //pointer (node link another node same node type???)  
};
```

NOTE: (ask yourself)

- Does node link to another node(s)? Often yes
- Does node store data? Always yes

Data structure declaration- (think hard about how to add new node in instantiate structure)

[Contains method to LINK up node such as AddAnotherNodeTo]

```
Class [dataType] {  
public:  
    ...  
    AddAnotherTo[DataType] //Instantiated data struct add node  
private:  
    //Root node pointer (root node link to another same node type)  
};
```

NOTE: (ask yourself)

- How to add another node? ANSWER is dependent on data structure property
 - BST → Sorting process. So go left go right etc
 - Stack → Push

Arrow notation:

```
[Pointer] -> [Data member] OR (*Pointer).DataMember
```

So

[Pointer] -> [Data member] = [Pointer2] -> [Data member]

Think of it as referring to [data member] and assigning [pointer2] data member

Understanding Big-O cheat sheet:

Data Structure	Time Complexity							
	Average				Worst			
	Access	Search	Insertion	Deletion	Access	Search	Insertion	Deletion
<u>Array</u>	$\theta(1)$	$\theta(n)$	$\theta(n)$	$\theta(n)$	$\theta(1)$	$\theta(n)$	$\theta(n)$	$\theta(n)$

Access: (related to searching) How does to access an *element @ a location in the data structure?

Search: How to loop through a data structure? Similar to access but not ever structure can access at point

Insertion: How to add an *element to a data structure

Deletion: How to add an *element to data structure

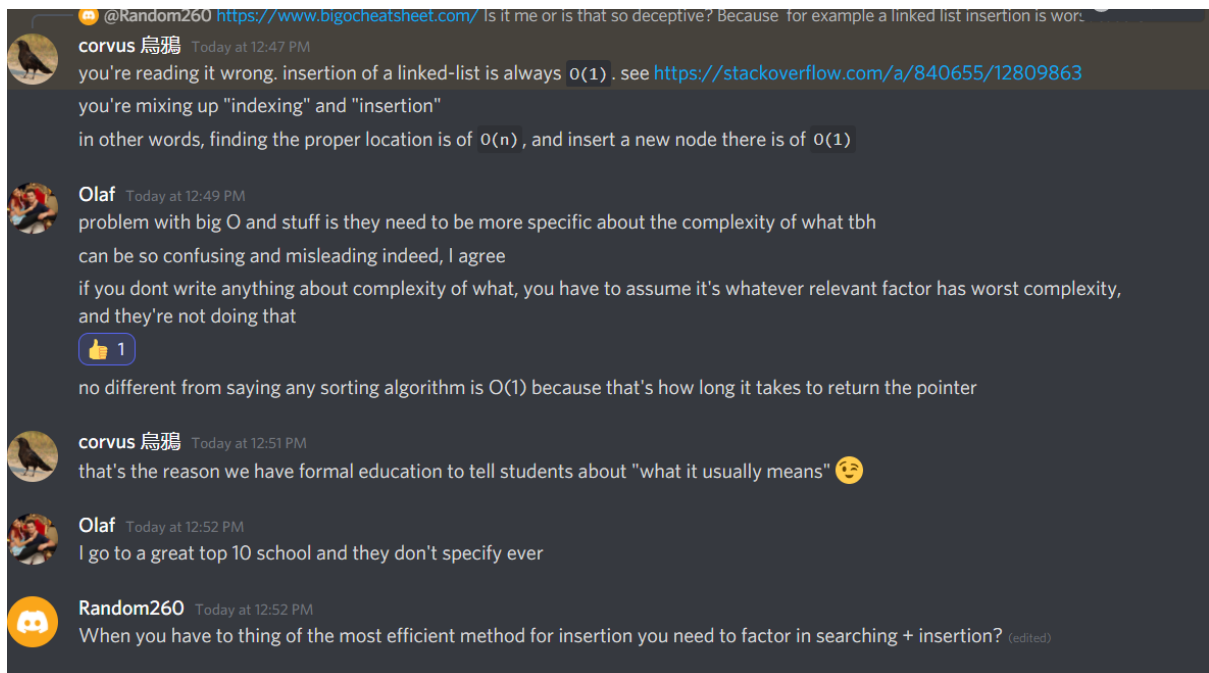

Worst means: Assume element to access/search is at the end of the data structure

So in an array, obviously accessing an element of an array is quickest $O(1)$

But searching is slow because we need to iterate through each element one by one

*Element/Node

Why Big(O) deceptive:

The insertion operation itself is $O(1)$, but the traversal to get to the point where you want to insert is going to be $O(n)$ worst case

Important: Consider in combination insertion + searching

Just realised it is. So for most cases if you want to insert lets say in middle you need to actually "add" insertion + searching. If only there was simple maths to compare

STL algorithms vs Raw loops?

Algorithm looks nicer

Find() is for single thing

Loop for iterating through all elements
